

Missouri's 25x'25 Energy Future

The Economic Impacts of a Renewable Electricity Standard and Carbon Payment Program

November 10, 2010

The Vision

By 2025, America's farms, forests and ranches will provide 25 percent of the total energy consumed in the United States, while continuing to produce safe, abundant and affordable food, feed and fiber.

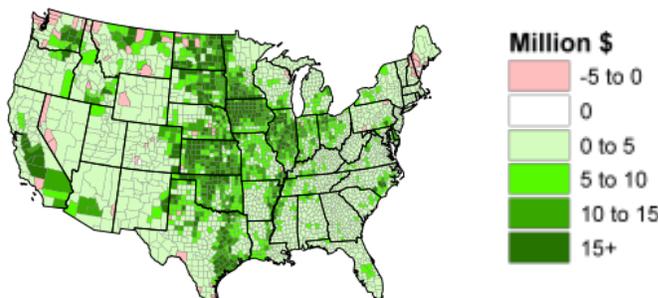

A National Study

An economic analysis conducted by researchers at the University of Tennessee on behalf of the 25x'25 Initiative outlines the impact of potential energy policy on America's farmers and foresters through the implementation of a national Renewable Electricity Standard (RES) and a carbon payment mechanism (CPAY). The study provides information on land use change, feedstock production, feedstock prices, farm income, carbon costs, payments for producers, and resulting national economic impacts.

The study assumes that the agriculture and forestry community are already working to meet the needs of the 36 billion gallon national Renewable Fuels Standard (RFS2) by 2022, a component of the Energy Independence and Security Act (EISA) enacted by Congress in 2007. The study evaluates a 25 percent RES to be met by 2025, however, with exceptions for small power retailers, hydropower sales, municipal solid waste sales and energy efficiency credits, the effective RES is 17 percent by 2025. A carbon payment mechanism is included for the following agriculture and forestry practices that capture and sequester carbon: conservation tillage, bioenergy crop production, afforestation, grassland management and methane capture.

Key Results from the National Study:

- Economic net returns to agriculture are projected to be positive in the EISA+RES+CPAY Scenario compared with the baseline and widespread across the United States;
- Positive national economic impacts are projected to provide an additional \$226 billion in economic activity, an addition of over 800,000 jobs and \$87 billion added to the nation's GDP when multiplier effects are included;
- Income from carbon payments and from market revenues are higher than any potential increase in the cost of inputs such as energy and fertilizer;
- Net carbon emissions are reduced 76 million tons of carbon dioxide equivalents;
- There will not be major shifts in commodity cropland use or major changes in crop and livestock prices.

Under the EISA+RES+CPAY Scenario, in 2025, positive agricultural net returns are scattered across the United States.

What Do These Mean?

Biofuel: Any liquid fuel produced from biomass. Biofuels sometimes are referred to as renewable fuels. However, renewable fuels also include biogas.

Biomass: Any biological matter that is available on a renewable or recurring basis, including agricultural crops and trees, wood and wood wastes and residues, plants (including aquatic plants), grasses, residues, fibers, and animal wastes, municipal wastes, and other waste materials.

Feedstock: Any crop grown to provide the raw material for producing biofuels, electricity, or other energy or biobased application or product.

RES: A renewable electricity standard—also referred to as a renewable portfolio standard (RPS)—requires certain electricity retailers to provide a minimum specified share of their total electricity sales from qualifying renewable power generation. RES policies can incorporate market-based mechanisms that enable obligated entities to buy or sell tradable renewable energy certificates (RECs) to demonstrate compliance.

Total Industry Output (TIO): the value of production across all industries in a region.

Woody biomass: Any material produced by trees, bushes and shrubs in any form of processing (chips, sawdust, leaves, needles, etc.).

A copy of this brochure, state data sheets and the complete report, "Implications of Energy and Carbon Policies for the Agriculture and Forestry Sectors," are available at: www.25x25.org.

Opportunities for Missouri

This study estimates that by 2025, Missouri's net farm income will increase \$678.77 million more than with the RFS2 alone. In meeting the RES, the agriculture and renewable energy sectors will provide positive economic impacts to the state economy, including a total industry output (TIO) of \$3.79 billion, and 4,509 new jobs in 2025. When multiplier effects are included TIO and jobs increase to \$5.5 billion and 16,636, respectively.

Electricity Production

Under a properly constructed RES, by 2025, Missouri could produce as much as 16.4 billion kWh of additional renewable electricity from biomass and wind. A breakdown of this production by biomass feedstock is shown in the figure to the right.

Land Use Impacts

An increasing demand for biomass feedstocks for energy production in Missouri will cause shifts in land use and the addition of new dedicated energy crops like switchgrass and fast growing trees like willow. By 2025, an estimated 1.66 million acres of dedicated energy crops are projected. For most states, the demand for bioenergy feedstocks will cause shifts to more intensely managed pasture land. Forest residues, thinnings and tree harvest will also play a significant role in meeting feedstock demands.

State Data Sheet

The accompanying data sheet provides detailed results from the national study at the state level for Missouri. The change in net farm income expresses the projected impacts of an RES and a carbon payment mechanism in addition to the changes in farm income from the EISA baseline. These numbers may appear insignificant in the short term, but increase as demand for biomass increases. The figures on land use change show acres planted and the change in acres planted as compared to the number of acres planted in the baseline. The estimated economic impacts of an RES and a carbon payment mechanism from the agriculture and renewable energy sectors on the state economy are presented. Agricultural economic impacts represent the land based impacts of renewable energy development, such as biomass feedstock production, wind lease payments, and electricity generation income from methane digesters. Renewable energy impacts represent the impacts of the development of a renewable energy industry, such as feedstock consumption, energy plants, and manufacturing.

By 2025, a properly constructed RES in Missouri could result in:

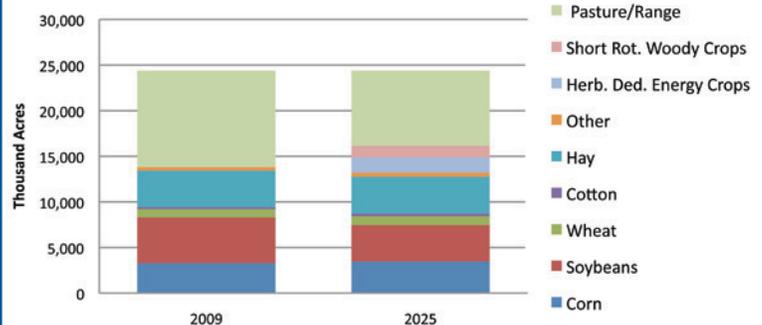

- \$678.77 M increase in net farm income over an RFS2 alone
- \$5.5 B increase in total economic impacts
- 16,636 additional jobs

Electricity Production from Biomass (Million kWh) for Missouri by Selected Year to Meet the 25x'25 Vision

Feedstock	2015	2020	2025
Corn Stover	0.0	0.0	115.4
Livestock	1139.9	1139.9	1139.9
Wood	317.5	444.3	3305.8
Energy Crop	5.0	88.6	9039.2
Byproduct Ethanol	234.7	397.4	1753.0
Total Biomass	1697.1	2070.1	15353.4

* Livestock consists of methane digesters plus any manure used for co-firing for electricity production.
